# Use Cases Specifications

## 1. Introduction

### 1.1 Purpose

This document provides a use case view of a suite of open source tools and services for learning, training and knowledge management labeled “**Repository-in-the-box**”, providing a set of freely accessible components to support the implementation, management and use of learning object repositories.

The present document is aimed as a bridge between users, designers, and the software development team that will build the intended suite of tools and components. It will also provide a coordination support to the software development plan managers and team leaders. It will be built in parallel with the development and evaluation of the system, its different versions providing a history of the system’s development.

### 1.2 Scope

This Use Cases Specification document provides a set of conceptual specifications for the complete infrastructure of the Repository-in-the box. These specifications are expressed in the UML graphical language and produced using the Rational Unified Process (RUP). They are based on a previously defined Vision document and will help orient the Software Architecture and the Software Development Plan of the eduSource project.

The complete set of eduSource architecture documents include.

- The eduSource Suite of Tools - Vision Document
- The eduSource Suite of Tools - Use Cases Specifications
- The eduSource Suite of Tools - Software Architecture
- The eduSource Suite of Tools - Glossary

### 1.3 Definitions, Acronyms, and Abbreviations

- DOI – Digital Object Identifier
- DRI – Digital Repositories Interoperability
- DRM – Digital Rights Management
- EML - Educational Modeling Language
- GUID – Globally Unique Identifier
- HTTP – HyperText Transfer Protocol
- LCMS – Learning Content Management System
- LMS – Learning Management System
- LD – Learning Design
- LO – Learning Object
- LOM – Learning Object Model
- LOR – Learning Objects Repository
- OAI – Open Archive Initiative
- ODRL - Open Digital Rights Language
- PMH - Protocol for Metadata Harvesting
- SCORM – Shareable Courseware Object Reference Model
- SOAP – Simple Object Access Protocol
- UML – Unified Modeling Language
- XML – eXtensive Markup Language
- Z39.50 – (Protocol for library information retrieval)

## 1.5 Overview of this document

This Use Cases Specification document groups UML diagrams and texts that provide a use-case view of requirements for the eduSource suite of tools, hereafter called “the system”.

- Section 2 present the objectives and contextual elements of the system. It is a summary of elements contained in the eduSource Vision document.
- Section 3 presents a set of use-case diagrams each containing several use cases interacting with the different users of the system. Use cases are grouped in a use-case diagram according to the roles of the main actors. The most important are described using sequential diagrams and some are further described in narrative form.
- Section 4 presents another user view organized around conceptual packages. Each package provides a way to classify some of the deliverables in the system. It also provides a conceptual basis for the Software Architecture document that will describe the decomposition of the system into subsystems, classes and class utilities.
- Section 5 presents some user-end view of the functions of some software components, based on the use cases descriptions in section 3 and organized around functional packages in section 4. These functional specifications lead to a proposed user interface.

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

## 2. Vision Goals and Constraints

EduSource Canada has adopted objectives in the form of design principles intended to govern the development of the architecture of a distributed learning object repository network. This section describes the software objectives and constraints deriving from these principles that have some significant impact on the use cases specifications.

1. *Support a true network model* as opposed to a silo model with separate repositories fed by publishers often on the basis of separate licensing agreements that increases the cost and restricts the choice of learning materials for all users and especially for small users.
2. *Use standards and protocols that are royalty free* to ensure that there is no a priori overhead cost incurred by agencies wishing to offer services compatible with eduSource.
3. *Implement and support emerging specifications* such as Cancore, whenever practical, and support the use of defined and controlled vocabularies so as to increase interoperability and functionality provided to end users searching and retrieving learning objects.
4. *Enable, don't require*, that is, try to achieve a higher level of consensus among core participants where possible without imposing it as a condition for entry among all participants.
5. *Infrastructure Layer and Service Layer*. The set of software tools comprising the infrastructure layer (described in the present document) will be developed and distributed as royalty-free open source. Over and above the infrastructure layer, components with increased functionality may be developed as free and open applications, or they may embody commercial and proprietary components.
6. *Distributed Architecture*. EduSource infrastructure and services are to be designed as a set of related components, each of which fulfills a specific function in the network as a whole. Any given software tool provided by eduSource may be replicated and offered as an independent service to provide robustness and ensure that no single service provider or software developer may exercise control over the network.
7. *An Open Marketplace*. eduSource will support the registration and indexing of various providers, this registration will be free and optional. eduSource will accommodate free content distribution, co-op or shared content distribution, and commercial fee-based content distribution.
8. *Multiple metadata description* of a given learning resource will ensure that potential users of learning resources can obtain and input multiple descriptions of that material.
9. eduSource will be seen as an *implementation of and an extension of the semantic web*, using sector-specific ontologies, into its own design, to support the widest reach possible and reduce the duplication of effort between developers working in specific domains and educators working in the same domain.
10. *Open Rights Management*. Where possible, the acquisition of rights and the exchange of funds will be automated. Multiple digital rights models will be provided for free materials, cooperative sharing and commercial offering on a per-view or subscription based model. No single rights agency will govern all transactions. A given provider of learning materials will work with one of many brokers who sell to multiple purchasers, and a given user may one of many agents who conduct transactions with multiple vendors.

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3. Use-Case Models

This section present use cases diagrams that represent some significant, central functionality of the final system, together with a large architectural coverage—they exercise many architectural elements or they stress or illustrate a specific, delicate point of the architecture.

The first three subsections will give a general view of the system (the eduSource suite of tools) from a user point of view.

Each of the following subsections will present one use case diagram grouping several use cases, together with the descriptions of their use cases in narrative form and/or followed by a sequence diagram. We have classified the use cases in five categories:

- Elearning Systems Interoperation
- Digital Repository Development
- Search and Select Learning Objects in Multiple Repositories
- Learning Design and Object Aggregation
- Digital Rights Management

#### 3.1 EduSource General Use Cases View

This first diagram presents the main actors that manipulate the eduSource suite of tools.

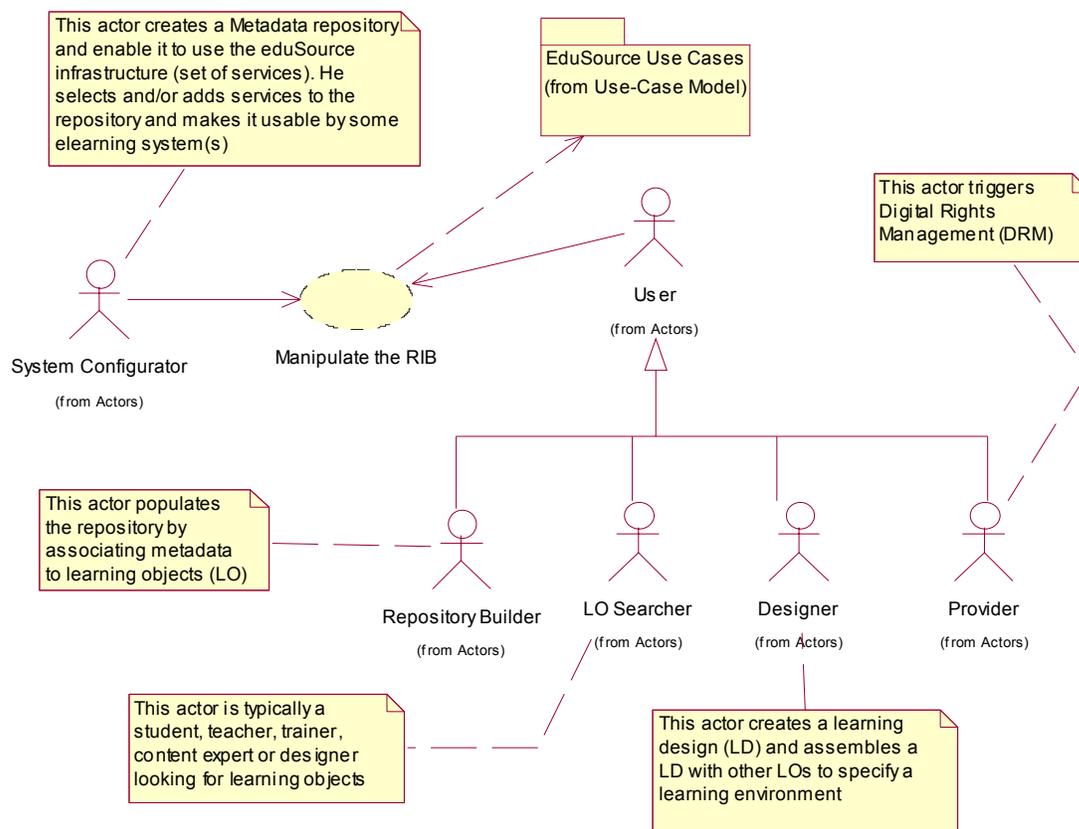

Figure 1 - General use case model

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.2 EduSource General scenario

The following sequence diagram presents an interaction view of the main actors with the system. These actors usually intervene in the following way even though other interactions patterns will generally occur. The System Configurator enables users to use the system by setting up a set of eduSource services. Then a Repository Builder can start constructing a learning object repository; a Designer can aggregate learning objects (LO) with a learning design and package it for the other users; a Publisher uses a DRM system; and finally a LO Searcher (teacher, trainer, learner, content expert, manager, etc.) searches multiple metadata repositories, displays objects (resources) and selects some for his/her own purposes.

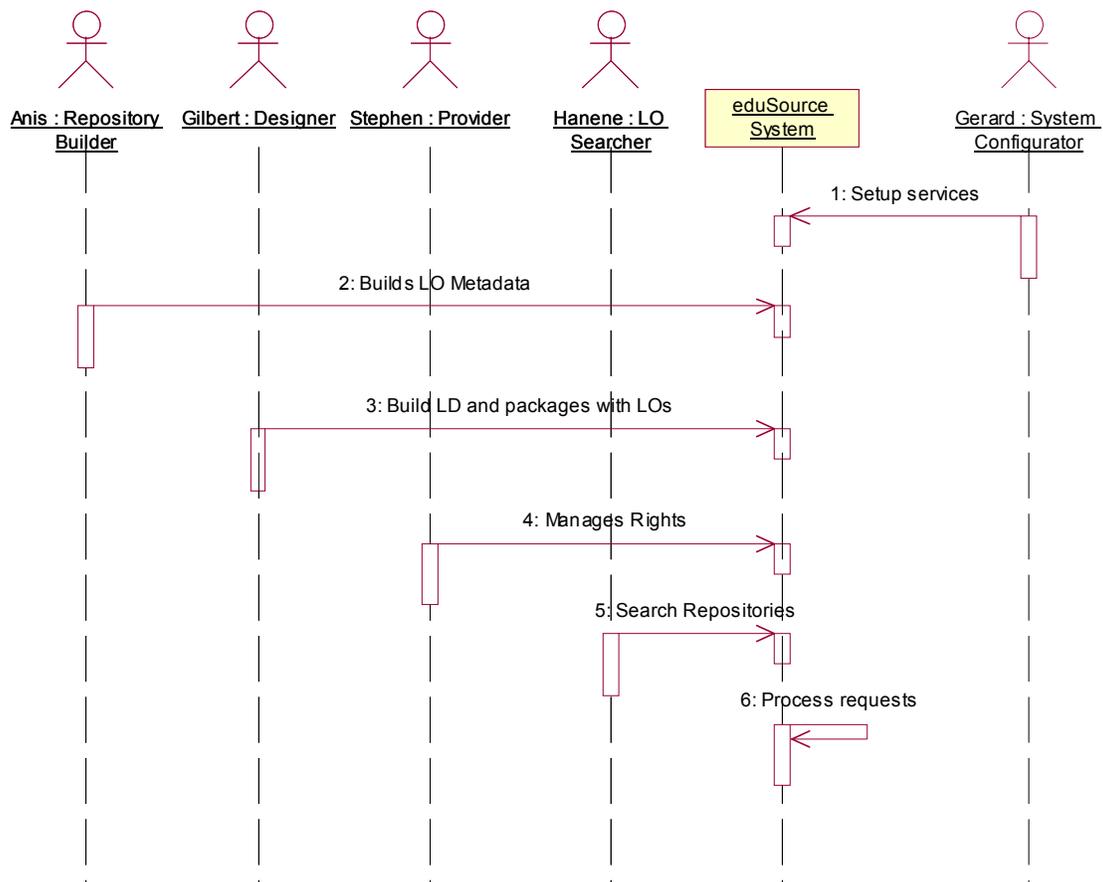

Figure 2 - EduSource general sequence diagram

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.3 EduSource Actors

This third general diagram shows the interaction between the main actors and secondary actors that will appear in the more detailed diagrams to be presented in the following sections.

We see here a user that wants to access Metadata Repositories through the use of Metadata Repository Services, possibly with the help an eLearning system (any LMS, LCMS, platform or computer agent). This user is either a Repository Builder, a LO Searcher, a LO Publisher or a Designer.

The Repository Builder needs the help of a System Configurator, using an eduSource Web services directory, to start building and maintaining a repository. The Repository Builder can also use a Search Result Display (SRD) to find objects to integrate in the repository. The SRD, and also the LO Searcher, both obtain their LOM (s) by using one or more methods, personified by actors called Harvester, Federator, or Distributor. The designer uses a Content Packager to aggregate learning designs with learning objects: the CP and the Launcher both interact with LO (resource) Repositories directly. Finally, the Publisher uses a Provider Broker and the LO searcher uses a Purchaser Broker, both communicating with an External Payment System, to protect IP while responding to requests from human Publishers or purchasers or learning objects.

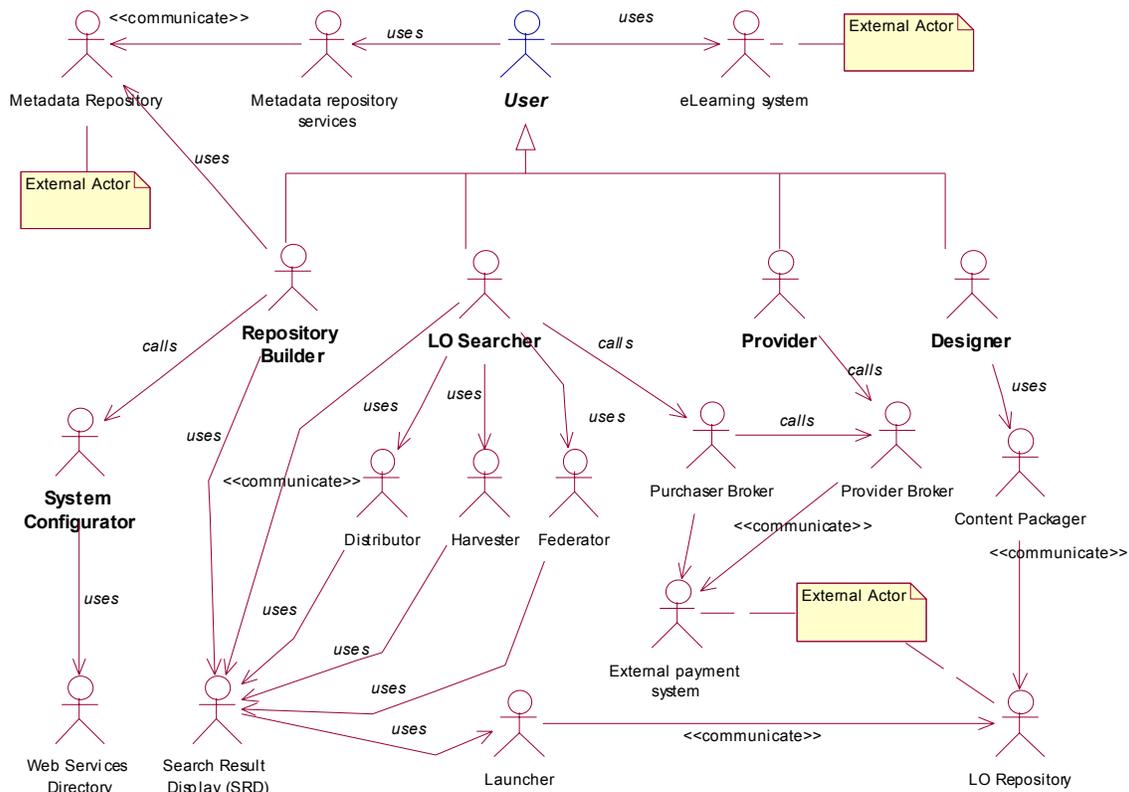

Figure 3 - EduSource actors relations diagram

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.4 Configuration and administration

This sub-section presents essential operations by which a *System Configurator* or an *eduSource Administrator* (usually a person) can make elearning systems (platforms, LMSs, LCMs, agents, etc.) inteoperate with the eduSource infrastructure services, and facilitate access to multiple Metadata Repositories and LO Repositories.

#### 3.4.1 Configuration/Administration Use Cases

The following use case diagram shows five main use cases. The first three concern the interaction of the System Configurator with a Web services directory, either to add new value-added services to the eduSource infrastructure or to make such services available to other users by assembling them in a user interface or integrating them in an existing eLearning system.

The two other use cases concern the configuration of repositories and eLearning systems to facilitate communication with the eduSource infrastructure. This is achieved by integrating an *EduSource Communication Language* (ECL) module. ECL is a metaprotocol using SOAP messaging for enabling repositories and eLearning systems to communicate together and with eduSource services together through the most common communication protocols. All the eduSource tools and services will be ECL enabled.

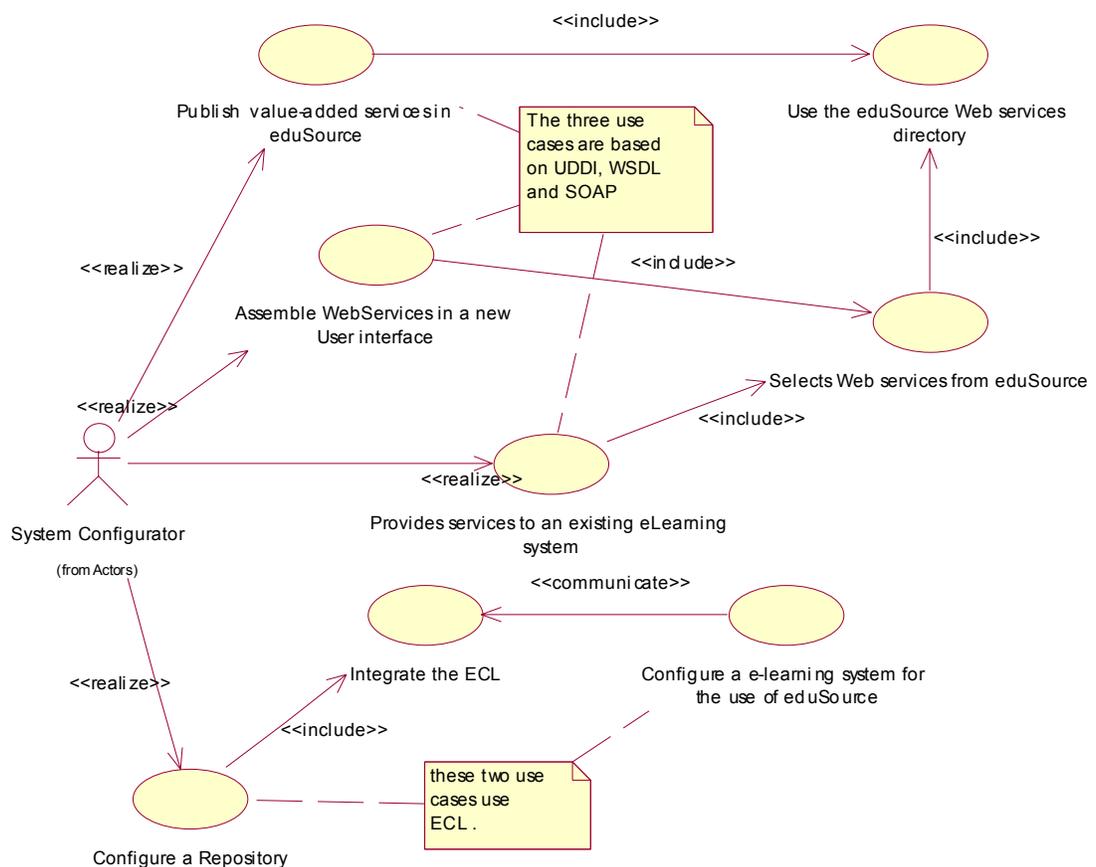

Figure 4 - Configuration use cases diagram

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.4.2 Configuration Sequence Diagram

This diagram illustrates a sequencing of the main interactions of a *System Configurator* with a Web services server through which the System Configurator will enable interoperability between a eLearning system and a user such as the Repository Builder. Such an actor can ask for eduSource services either to the eLearning system, or directly to the System Configurator if he/she doesn't use a eLearning system.

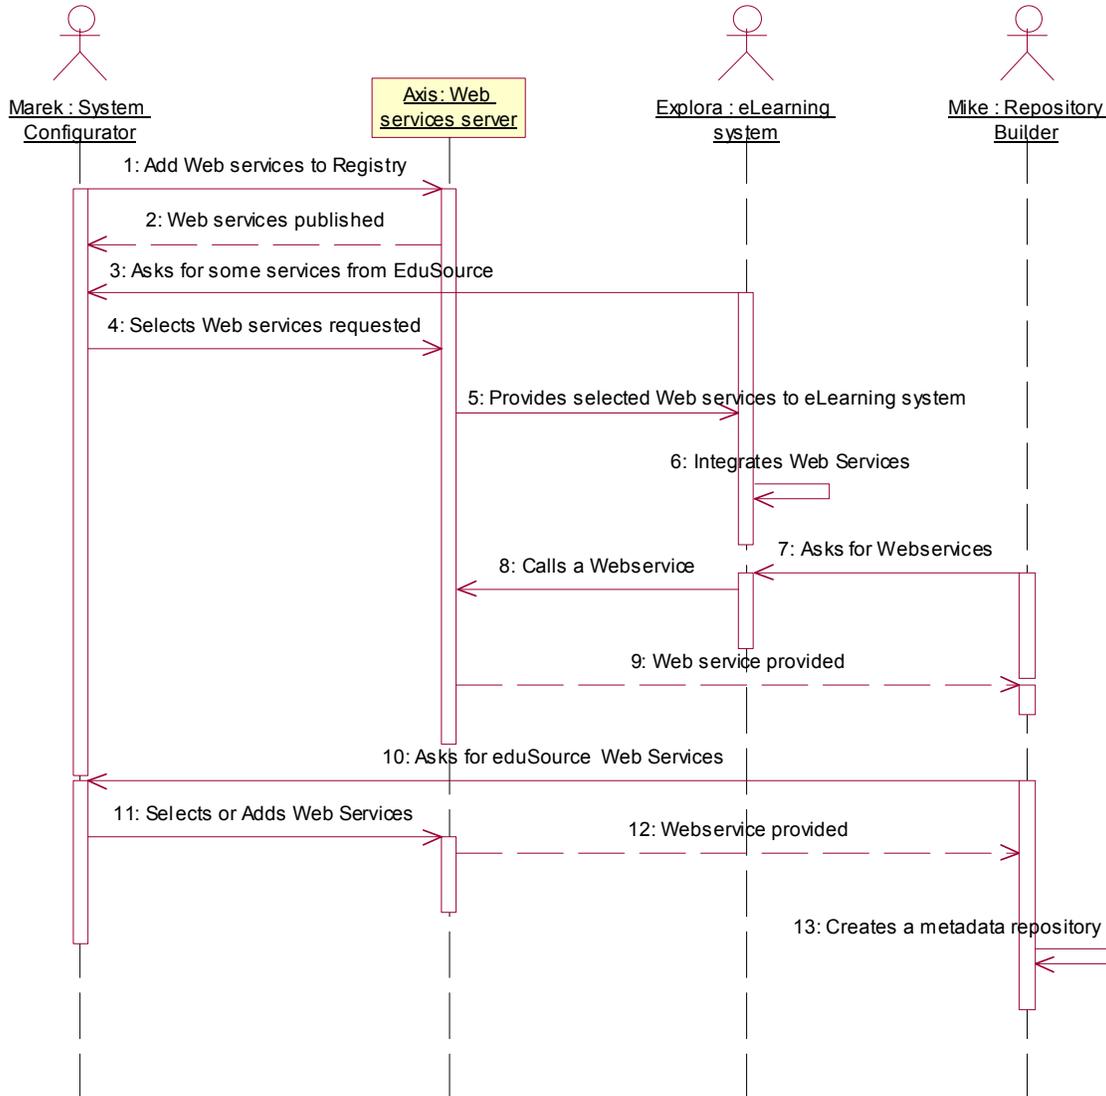

Figure 5 - Configuration sequence diagram

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.5 Metadata Repository Development and Maintenance

This sub-section describes essential operations by which a *Repository Builder*, generally a person, builds a metadata repository, makes it available on the Web to other users, manages and maintains its components.

#### 3.5.1 Build and Maintain Use Cases

Basically, the *Repository Builder* can create or suppress a repository, manage metadata records including publishing new LOM records, modifying or suppressing such records.

Before this can be done, a LO must be found on the Web, on a LAN, or through a search in other Metadata repositories. This last case involves a LO searcher that will be described in section 3.5 of this document and it leads to modifying existing metadata records or adding a different LO description to the metadata repository. On the other hand, the Repository Builder can use usual techniques to find an object on the Web or on a LAN that is not already described by metadata or is not obtainable through metadata search methods. This case can lead to adding a new record to the metadata repository. In both cases, once a LO has been found and selected, a metatagging tool must be used to enter metadata in the repository.

The Repository Builder also manages the access rights to users, either to the whole repository, to groups of metadata records, to individual records or to learning objects referenced by the metadata. This use case must be distinguished from the Publisher (DRM) use cases that will be described in section 3.8. In fact, here, the Repository Builder takes care of the response of the Repository to requests made by a user. This user might be a purchaser having obtained rights through the DRM system, or a Publisher that has set conditions to use some learning objects. When a metadata record contains restrictions, the Repository Builder must obtain a credential made available by the Publisher to a purchaser, to enable the use of the corresponding object by the purchaser.

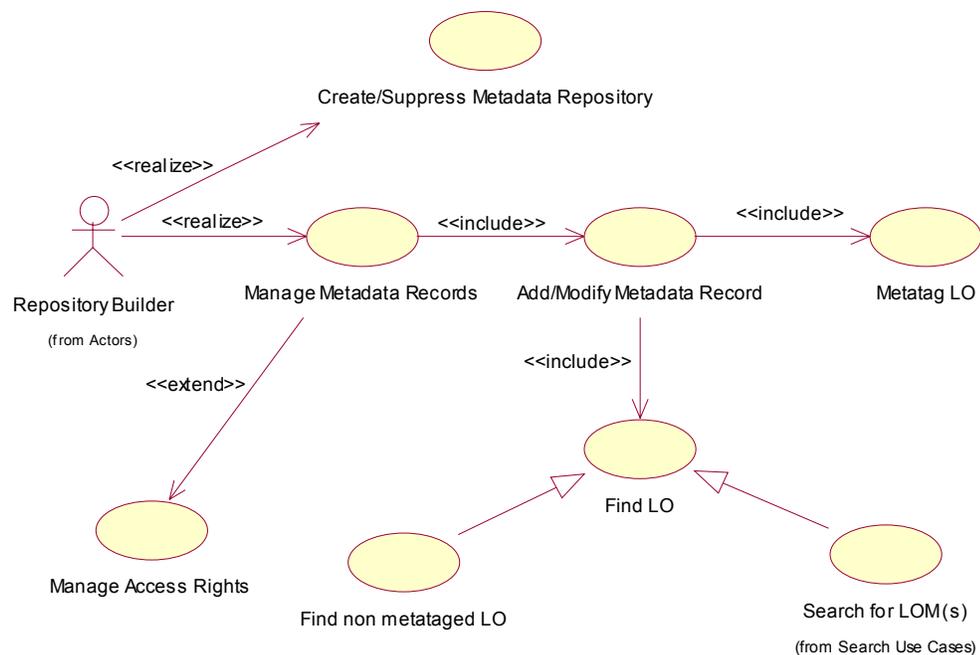

Figure 6 - Build use cases diagram

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.5.2 Build and Maintain Sequence Diagram

The following sequence diagram shows the main interactions of a Repository Builder with a Metadata Repository. In the process, this actor interacts with LOM (s) resulting from a search in possibly multiple repositories, or with raw learning objects obtained through the Web or through browse and search on a Local Area Network (LAN).

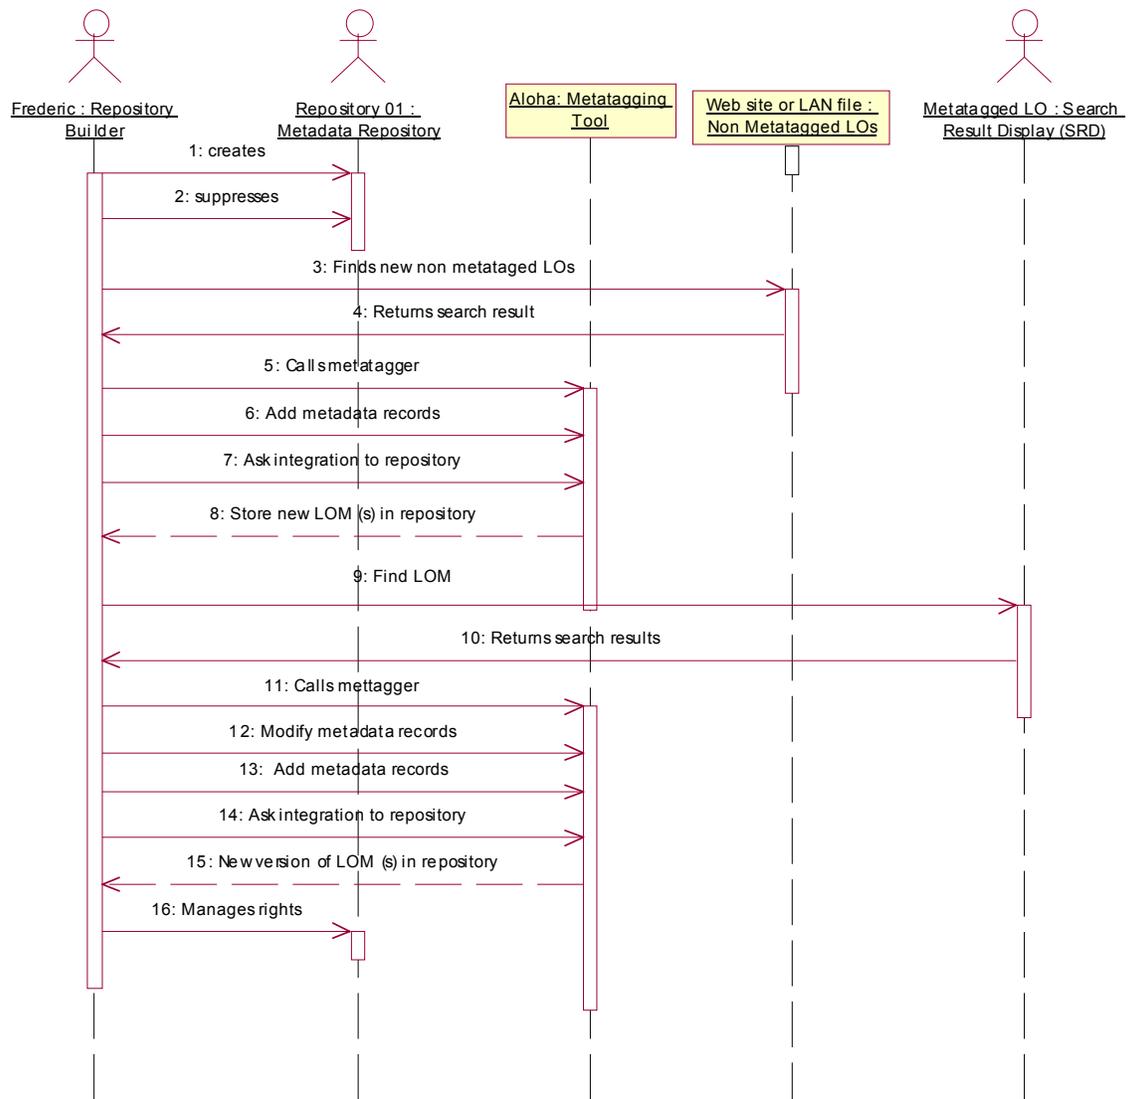

Figure 7 - Build repository sequence diagram

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.6 Search and Select Learning Objects in Multiple Repositories

This sub-section describes essential operations by which a LO Searcher (a person or a software agent) can select a search method, query a network of learning object repositories (LORs) using that method, obtain and display a set Learning Object Metadata (LOM), see the corresponding objects, and finally select one or more objects whose addresses are stored as hyperlinks in a Web page.

#### 3.6.1 Search and Select Use Cases

Most often the LO Searcher will be a person (learner, trainer, designer, manager), but it may very well be software running as part of an LCMS or an agent launching a scheduled Intelligent Search Agent on behalf a human user. The other actors in the following diagram are software agents or tools provided as services to the LO Searcher.

The diagram presents 6 use cases. The first one, Display Metadata & Objects, captures the LO Searcher's goal to create a Web page containing links to a set of selected learning objects; this page is generated by a Search Result Display actor using a Display Metadata and Objects tool. This use case is extended by a generic search service use case that can trigger one, two or three search methods. These methods are shown on the diagram as sub-cases of the Search for LOM (s) use case. Actors called the Federator, the Harvester and the Distributor are responsible for these three specialized search use cases:

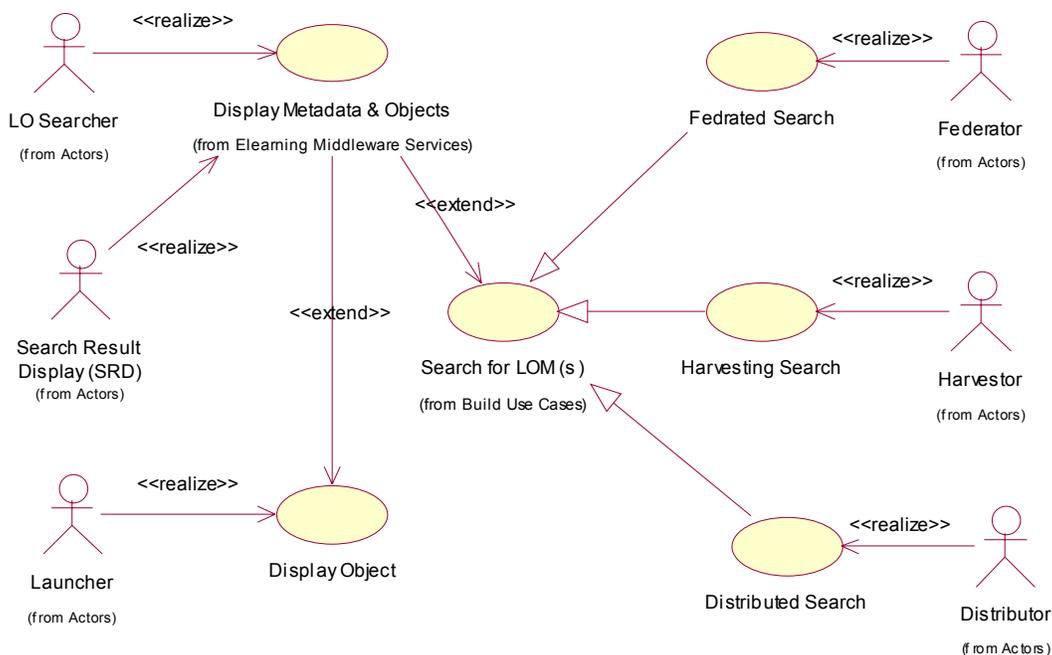

Figure 8 - Search and display uses cases

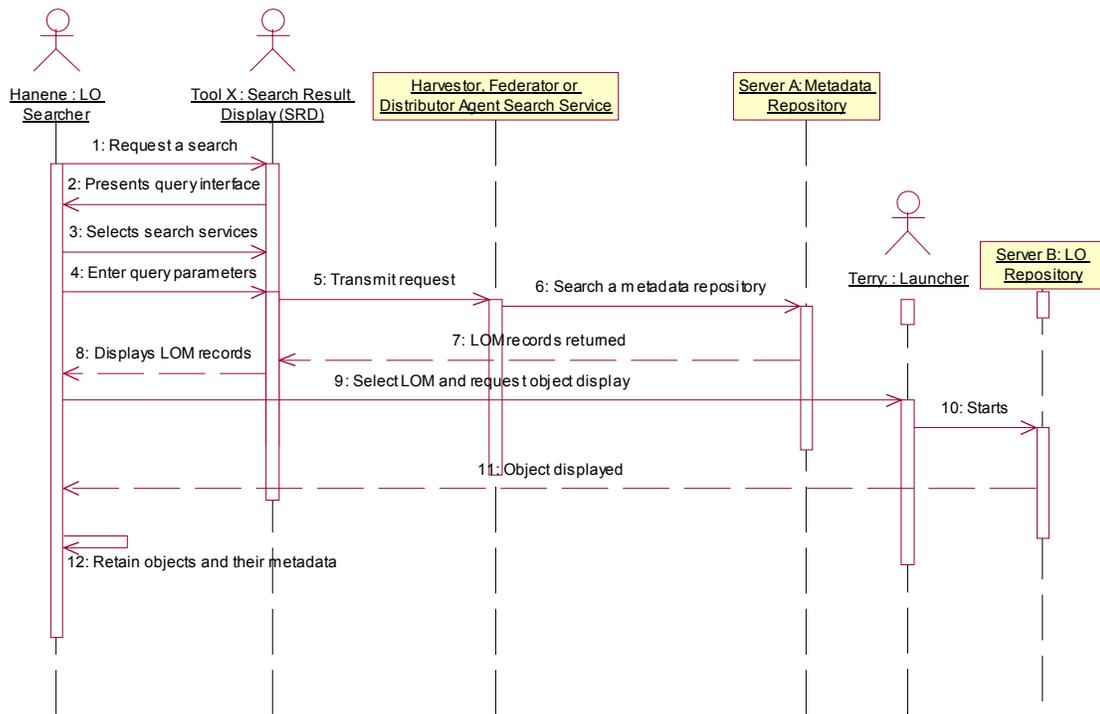

#### 3.6.2 General Display Sequence Diagram

The following sequence diagram present the general search and display operations. The LO searcher uses a Search Result Display tool to start a search. The tool present a choice of search methods and corresponding query interfaces. The LO search selects certain search methods and enter the query parameters

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

Whatever search methods are used, a resulting list of learning object metadata (LOMs) records is presented to the LO Searcher who can ask to see any of them. An actor called the Launcher is responsible to contact a server for that object and display the object.

The LO searcher can then retain the object and its metadata record in a list for further use.

**Figure 9 – General Search and Display sequence diagram**

We now present a detailed narrative of this use case

<b>Description</b>	This use case presents a high-level process through which a LO Searcher uses the eduSource software services to find, view and select one or more learning objects, their address being retained in a Web page.
<b>Goal in Context</b>	To provide users (designers, learners, trainers, managers, etc) with diversified ways to find and aggregate a set of related learning objects
<b>Preconditions</b>	The LO Searcher has access freely (no DRM component involved in this case) to one or more learning object repositories on the Internet.
<b>Success End Condition</b>	The LO Searcher has retained a (possibly empty) set of learning objects and the system has displayed hyperlinks to these objects in a Web page.
<b>Failed End Condition</b>	No Web page is produced because either search has failed or the display has failed.
<b>Primary Actor</b>	<b>LO Searcher:</b> a person (or a software application) wanting to search a network of metadata repositories. Most often the LO Searcher will be a person, but it may very well be software running as part of an LCMS or an agent launching a scheduled Intelligent Search Agent on behalf a human user.

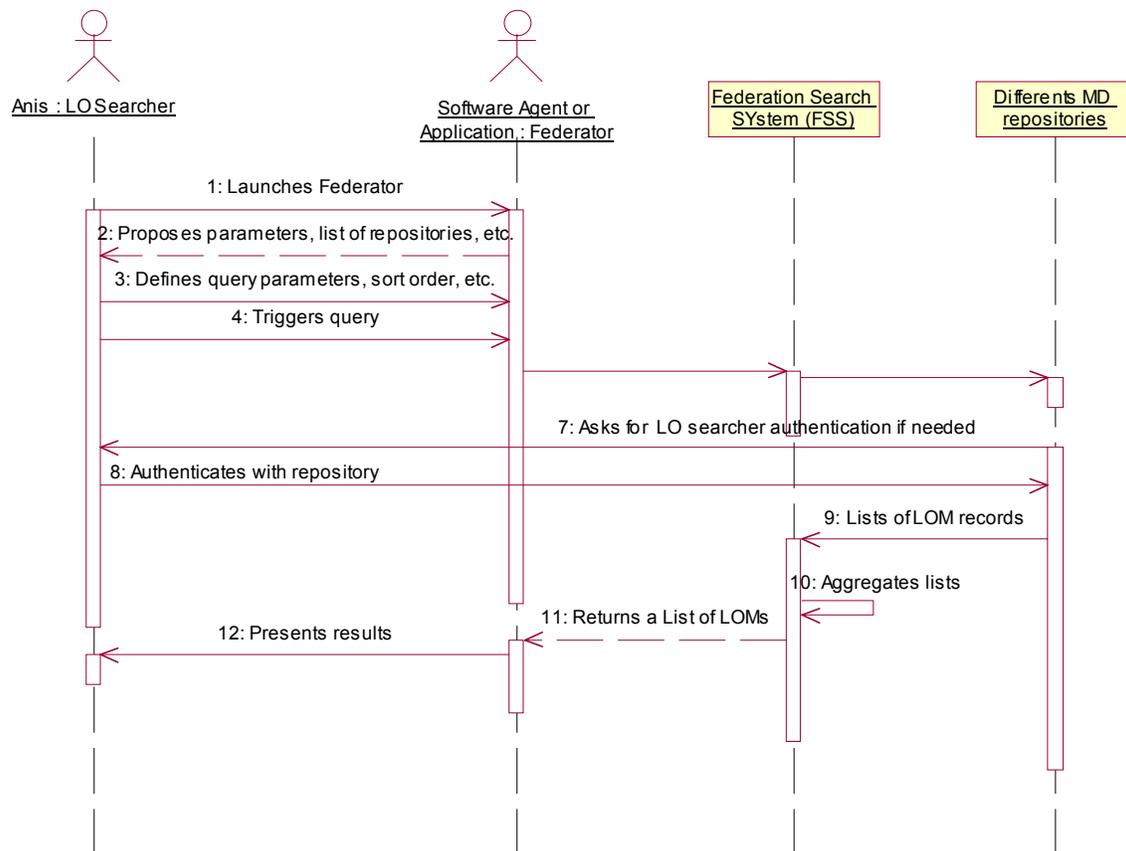

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

<b>Secondary Actors</b>	<b>Search Result Display (SRD):</b> an eduSource tool <b>One or more search service</b> that can be a federator, a harvester or a distributed search. <b>Launcher:</b> an actor that can display a learning object or a content package in a viewable format																								
<b>Trigger</b>	A LO Searcher calls upon the SRD service																								
<b>FLOW OF EVENTS</b>	<table> <thead> <tr> <th>Step</th> <th>Action</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>The LO Searcher finds the address of a SRD service in a registry</td> </tr> <tr> <td>2</td> <td>The SRD tools presents a choice of search methods to the LO searcher.</td> </tr> <tr> <td>3</td> <td>The LO Searcher selects a search service or a combination of search services</td> </tr> <tr> <td>4</td> <td>The SRD presents query interfaces corresponding to the selected search services</td> </tr> <tr> <td>5</td> <td>The LO Searcher enters the query and validates</td> </tr> <tr> <td>6</td> <td>The SRD calls the selected search services (SSs)</td> </tr> <tr> <td>7</td> <td>The SSs search the Metadata Repository network and return lists of Metadata Records to the SRD</td> </tr> <tr> <td>8</td> <td>The SRD displays the list of Metadata Record names and addresses to the LO Searcher</td> </tr> <tr> <td>9</td> <td>The LO Searcher asks the SRD to display the Metadata of a selected object</td> </tr> <tr> <td>10</td> <td>The LO Searcher asks the Launcher to display selected objects</td> </tr> <tr> <td>11</td> <td>The LO Searcher asks the SRD to group the retained objects and their Metadata Records hyperlinks in a Web page</td> </tr> </tbody> </table>	Step	Action	1	The LO Searcher finds the address of a SRD service in a registry	2	The SRD tools presents a choice of search methods to the LO searcher.	3	The LO Searcher selects a search service or a combination of search services	4	The SRD presents query interfaces corresponding to the selected search services	5	The LO Searcher enters the query and validates	6	The SRD calls the selected search services (SSs)	7	The SSs search the Metadata Repository network and return lists of Metadata Records to the SRD	8	The SRD displays the list of Metadata Record names and addresses to the LO Searcher	9	The LO Searcher asks the SRD to display the Metadata of a selected object	10	The LO Searcher asks the Launcher to display selected objects	11	The LO Searcher asks the SRD to group the retained objects and their Metadata Records hyperlinks in a Web page
Step	Action																								
1	The LO Searcher finds the address of a SRD service in a registry																								
2	The SRD tools presents a choice of search methods to the LO searcher.																								
3	The LO Searcher selects a search service or a combination of search services																								
4	The SRD presents query interfaces corresponding to the selected search services																								
5	The LO Searcher enters the query and validates																								
6	The SRD calls the selected search services (SSs)																								
7	The SSs search the Metadata Repository network and return lists of Metadata Records to the SRD																								
8	The SRD displays the list of Metadata Record names and addresses to the LO Searcher																								
9	The LO Searcher asks the SRD to display the Metadata of a selected object																								
10	The LO Searcher asks the Launcher to display selected objects																								
11	The LO Searcher asks the SRD to group the retained objects and their Metadata Records hyperlinks in a Web page

### 3.6.3 Federated Search Sequence diagram

**Figure 10 - Federated search sequence Diagram**

We now present a detailed narrative of this use case.

<b>Description</b>	This use case details the process through which a Federator interacts within eduSource to search a network of Metadata repositories and to locate a set of LOMs.
<b>Goal in Context</b>	The goal is to create a service for a LO Searcher (teacher, student ,course developer or software agent) to search for a learning object across multiple repositories, providing an aggregated result list of metadata records in return.
<b>Preconditions</b>	The LO Searcher must have access to the Internet.
<b>Success End Condition</b>	The Federator possesses a (possibly empty) result list of learning objects from a variety of repositories which meet a search criterion provided by the LO Searcher.
<b>Failed End Condition</b>	The Federator has not gained possession of any result list, the search aborts or returns an incomplete list before searching all selected sites
<b>Primary Actor</b>	<b>Federator:</b> a software agent responsible for providing the interaction between the LO Searcher and the Federated Search System (FSS). The Search Agent may be extremely minimal - it might just be a web browser - or it could be an Artificially Intelligent Agent

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

responsible for searching and harvesting metadata applicable to a students' course load or other general educational requirements defined by the LMS. It is the responsibility of the Search Agent to work within the framework of the LMS when interacting with a human user while generating queries or presenting results.

**Secondary Actors**

**LO Searcher:** a person (or a software application) wanting to search a network of metadata repositories. Most often the LO Searcher will be a person, but it may very well be software running as part of an LMS or an agent launching a scheduled Intelligent Search Agent on behalf a human user.

**Federated Search System (FSS):** a software interface that can access a set of metadata repositories, search each one according to their conditions and returns a set of Metadata Records.

**Trigger**

The LO Searcher, directly or using the Search Result Display tool asks the Federator to query a network of metadata repositories.

**FLOW OF EVENTS**

- | Step | Action  |
|------|---|
| 1    | A LO Searcher launches the Federator, directly or through the SRD.  |
| 2    | The Federator selects search parameters appropriate for this LO Searcher: This includes proposing a list of eduSource repositories available for searching given the DRM rights and classification of the LO Searcher. Parameters include methods for general keyword searching, as well as facilities for substring and full/partial-match phrase searching in general or specific metadata fields or groups of fields (ie, people). Optional facilities would include those for Natural Language Processing, or conducting searches and "joins" across the actual learning object content and it's metadata.. |
| 3    | The LO Searcher selects MD repositories, defines query parameters such as search priorities et presentation order.  |
| 4    | The LO Searcher triggers the query  |
| 5    | The Federator submits the query to the Federated Search System (FSS). This can be done using Xform search query   |
| 6    | The FSS processes the form submission generating a separate query for each repository. The format of these queries will depend upon what protocols the FSS instance supports. They will most likely be XQueries according to the IMS DRI spec, but could also be in the form of z39.50, or repository specific www-form-url-encoded keyword searches. The FSS can even launch it's own Search Agent for querying other Federated Search Systems.  |
| 7    | Depending on the LOM requested, some repositories can ask the LO searcher to authenticate with the repository.  |
| 8    | The LO searcher authenticates as requested  |
| 9    | The repositories provide lists of LOM records to the FSS.   |
| 10   | The FSS aggregates the results - collating multiple results sharing the same learning object global unique identifiers (GUID's), sorting them according to LO Searcher preferences etc.   |
| 11   | The FSS returns the aggregated result list, in XML Format to the Federator  |

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

performing the query.

- 12 The Federator makes these results available to the LO Searcher directly or to the SRD (depending on the origin of the call).

**EXTENSIONS Step Branching Action**

- 5a, 12a If the LO Searcher is a person calling directly the Federator, instead of returning XML code, the Federator returns a Web page using CSS and XSLT. (If the LO Searcher has called a search through the SRD, the SRD takes care of the presentation of results).

**VARIATIONS Step Branching Action**

- 8a If the LO searcher decides to not authenticate with all or some of the MD repositories. The corresponding LOM will not be returned to the FSS at step 9. But action will proceed.
- 10 a If the FSS returns an empty list to the Search Agent, it may, at the LO Searchers option, adjust the parameters of the search to broaden the scope. The converse is also true in that the Agent, the FSS, or a repository may further restrict the scope of the query to narrow the result list - perhaps by removing common or unnecessary keywords from the query, etc. The Federator may also restrict results by specifying time or resource limits in the query parameters to the FSS.

**COMMENTS** Authors: Chris Hubick and Terry Anderson

XForms is suggested for this protocol; this would most likely require (or strongly benefit from) defined XForm control names and types.

In non-Xquery searches, standards for form control names/types and other interactions will be needed.

Should the FSS result list use Xschema?

Should agent control, display of returned metadata with expandable fields such as Cancore general, lifecycle etc. or should this be handled by the FSS, based upon parameters passed from the Agent with the search request?

### 3.6.4 Harvesting Search Sequence diagram

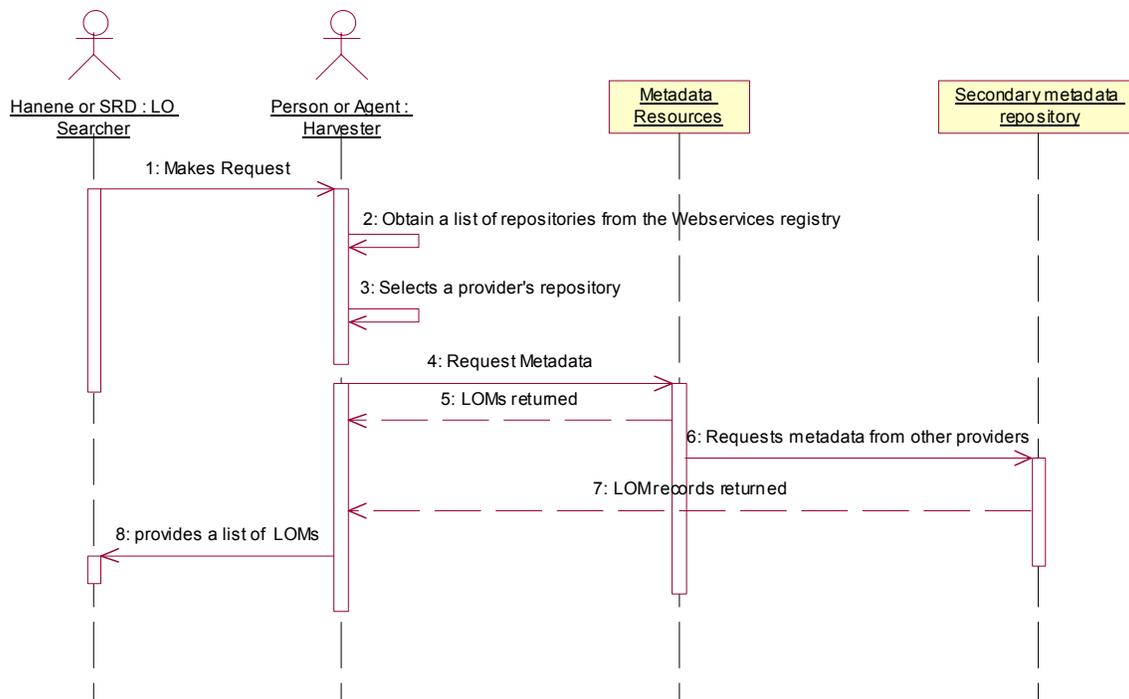

Figure 11 - Harvesting search sequence diagram

We now present a detailed narrative of this use case.

<b>Description</b>	A Harvester is operated by a service provider as a means of collecting metadata from repositories, here defined as network accessible servers that can process the 6 OAI-PMH requests (GetRecord, Identify, ListIdentifiers, ListMetadatFormats, ListRecords, ListSets). An acceptable alternative to OAI-PMH is to use D-Space repositories.
<b>Goal in Context</b>	To provide LO-Searchers with a way to use a Harvester as a search service and enable resource Publishers (commercial and non-commercial) with a simple way to make their resources available for use through the eduSource network.
<b>Preconditions</b>	The LO Searcher has access to a Harvester on his/her workstation. At least one learning resource Publisher has created at least one metadata repository and a corresponding resource repository available to Harvesters in a Registry that list all such repositories available for harvesting.
<b>Success End Condition</b>	The LO Searcher has located a resource through a Harvester from at least one learning resource Publisher.
<b>Failed End Condition</b>	No search results can be obtained from the harvesting system.
<b>Primary Actor</b>	<b>Harvester:</b> a client application that issues OAI-PMH compliant requests and makes metadata available to LO Searchers.

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

<b>Secondary Actors</b>	<p><b>Resource Publisher</b> a person (or a software agent) creating repositories for the harvesting system.</p> <p><b>Registry service:</b> a service making available a list of metadata and resource repositories.</p>																		
<b>Trigger</b>	The LO searcher makes a request to a Harvester on his client station, directly or through a SRD (Search Results Display) tool.																		
<b>FLOW OF EVENTS</b>	<table> <thead> <tr> <th>Step</th> <th>Action</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>LO searcher or SRD makes a request to a Harvester</td> </tr> <tr> <td>2</td> <td>Harvester requests list of repositories from the registry service</td> </tr> <tr> <td>3</td> <td>Harvester selects a Publisher's repository</td> </tr> <tr> <td>4</td> <td>Harvester requests all metadata for each resource listed in the list of metadata resources.</td> </tr> <tr> <td>5</td> <td>Harvester returns LOM</td> </tr> <tr> <td>6</td> <td>The harvester requests metadata from other Publishers having repositories listed in the Registry.</td> </tr> <tr> <td>7</td> <td>Harvester returns more LOMs</td> </tr> <tr> <td>8</td> <td>The harvester provides a list of metadata records matching values set originally by the LO searcher or the SRD, harvest from the selected Publisher or from third party repositories..</td> </tr> </tbody> </table>	Step	Action	1	LO searcher or SRD makes a request to a Harvester	2	Harvester requests list of repositories from the registry service	3	Harvester selects a Publisher's repository	4	Harvester requests all metadata for each resource listed in the list of metadata resources.	5	Harvester returns LOM	6	The harvester requests metadata from other Publishers having repositories listed in the Registry.	7	Harvester returns more LOMs	8	The harvester provides a list of metadata records matching values set originally by the LO searcher or the SRD, harvest from the selected Publisher or from third party repositories..

### 3.6.5 Peer-to-Peer Distributed Search Sequence diagram

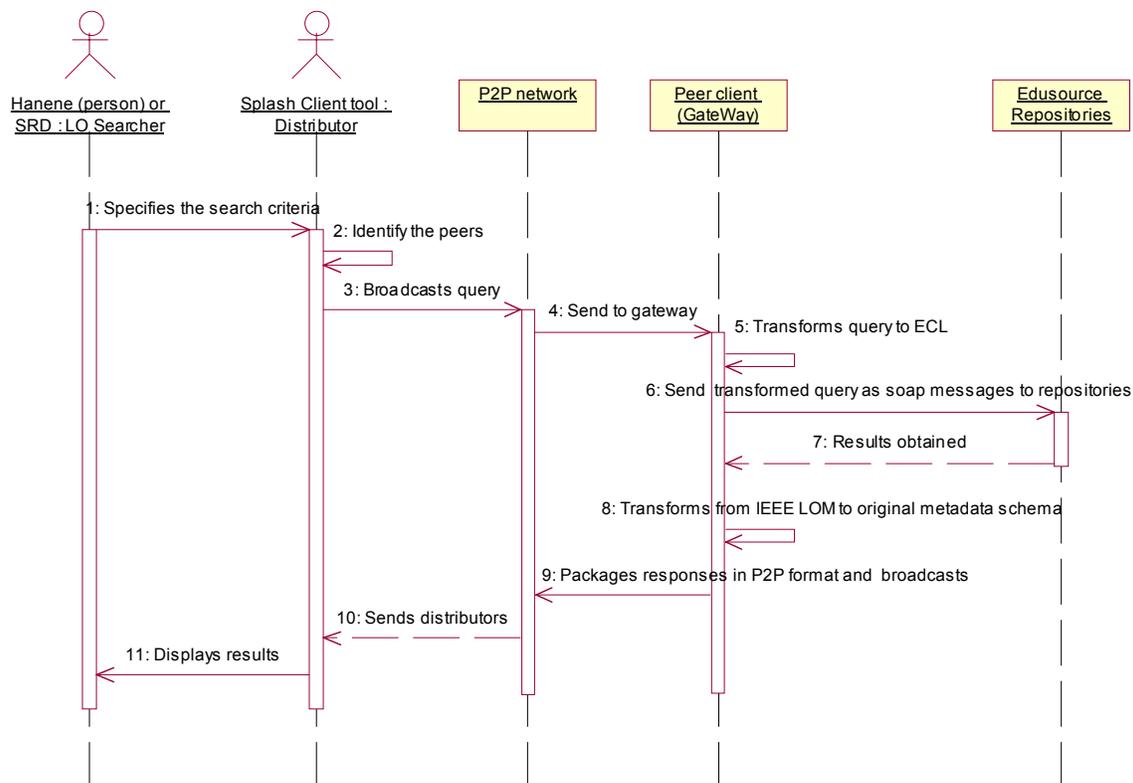

Figure 12 - Distributed P2P search sequence diagram

We now present a detailed narrative of this use case.

<b>Description</b>	The user (LO searcher) issues a search request to P2P network, directly or though the Search Result Display tool. The query is transformed and sent to the repository (-ies) that can be reached through the eduSource gateway. The results from the repository are received by the gateway and after transformation are propagated via P2P network to the user.
<b>Goal in Context</b>	The LO searcher receives metadata results from eduSource reachable repositories on peers and LO Publisher's servers.
<b>Preconditions</b>	The peer is connected to P2P network The gateway between P2P network and eduSource is configured and running Some eduSource repositories are open for search requests
<b>Success End Condition</b>	The metadata records from the eduSource reachable repositories are received by the peer and displayed to the user
<b>Failed End Condition</b>	No results reach the LO searcher, even when preconditions are met.

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

<b>Primary Actor</b>	<b>Distributor:</b> a PtoP distributed search agent on the client																						
<b>Secondary Actors</b>	<b>LO Searcher:</b> a person (or a software application) wanting to search a network of metadata repositories. Most often the LO Searcher will be a person, but it may very well be software running as part of an LMS or an agent launching a scheduled Intelligent Search Agent on behalf a human user.																						
<b>Trigger</b>	The LO Searcher or the SRD asks for a search to a P2P client																						
<b>FLOW OF EVENTS</b>	<table> <thead> <tr> <th>Step</th> <th>Action</th> </tr> </thead> <tbody> <tr> <td>1</td> <td>The LO Searcher or the SRD specifies the search criteria to the Distributor (SPLASH or other peer client connected to the P2P network).</td> </tr> <tr> <td>2</td> <td>The distributor identifies the peers to which it will broadcast the query (based on the peer selection mechanism which is part of the P2P network design) and broadcasts the query.</td> </tr> <tr> <td>3</td> <td>The query is broadcasted through the P2P network.</td> </tr> <tr> <td>4</td> <td>The query reaches the peer performing a function of gateway between eduSource and the P2P system. The gateway performs the following operations: <ul style="list-style-type: none"> <li>— Transforms the query from the P2P transport protocol to ECL protocol using XQuery specification (temporarily Xpath will replace XQuery)</li> <li>— If required, maps the metadata schema used within the P2P network to IEEE LOM (this step is omitted if the P2P system uses CanCore as is the case with SPLASH)</li> </ul> </td> </tr> <tr> <td>5</td> <td>Sends a SOAP message containing the transformed query to the eduSource repositories and awaits for the responses.</td> </tr> <tr> <td>7</td> <td>Results are returned to the gateway</td> </tr> <tr> <td>8</td> <td>After response from the eduSource repositories are received, the gateway transforms the results from the IEEE-LOM to the original request format</td> </tr> <tr> <td>9</td> <td>The gateway transform the results in P2P format</td> </tr> <tr> <td>10</td> <td>The results are propagated back via the P2P network when they eventually reach the originating peer (the Distributor).</td> </tr> <tr> <td>11</td> <td>The Distributor displays results to the LO searcher directly or through the SRD</td> </tr> </tbody> </table>	Step	Action	1	The LO Searcher or the SRD specifies the search criteria to the Distributor (SPLASH or other peer client connected to the P2P network).	2	The distributor identifies the peers to which it will broadcast the query (based on the peer selection mechanism which is part of the P2P network design) and broadcasts the query.	3	The query is broadcasted through the P2P network.	4	The query reaches the peer performing a function of gateway between eduSource and the P2P system. The gateway performs the following operations: <ul style="list-style-type: none"> <li>— Transforms the query from the P2P transport protocol to ECL protocol using XQuery specification (temporarily Xpath will replace XQuery)</li> <li>— If required, maps the metadata schema used within the P2P network to IEEE LOM (this step is omitted if the P2P system uses CanCore as is the case with SPLASH)</li> </ul>	5	Sends a SOAP message containing the transformed query to the eduSource repositories and awaits for the responses.	7	Results are returned to the gateway	8	After response from the eduSource repositories are received, the gateway transforms the results from the IEEE-LOM to the original request format	9	The gateway transform the results in P2P format	10	The results are propagated back via the P2P network when they eventually reach the originating peer (the Distributor).	11	The Distributor displays results to the LO searcher directly or through the SRD
Step	Action																						
1	The LO Searcher or the SRD specifies the search criteria to the Distributor (SPLASH or other peer client connected to the P2P network).																						
2	The distributor identifies the peers to which it will broadcast the query (based on the peer selection mechanism which is part of the P2P network design) and broadcasts the query.																						
3	The query is broadcasted through the P2P network.																						
4	The query reaches the peer performing a function of gateway between eduSource and the P2P system. The gateway performs the following operations: <ul style="list-style-type: none"> <li>— Transforms the query from the P2P transport protocol to ECL protocol using XQuery specification (temporarily Xpath will replace XQuery)</li> <li>— If required, maps the metadata schema used within the P2P network to IEEE LOM (this step is omitted if the P2P system uses CanCore as is the case with SPLASH)</li> </ul>																						
5	Sends a SOAP message containing the transformed query to the eduSource repositories and awaits for the responses.																						
7	Results are returned to the gateway																						
8	After response from the eduSource repositories are received, the gateway transforms the results from the IEEE-LOM to the original request format																						
9	The gateway transform the results in P2P format																						
10	The results are propagated back via the P2P network when they eventually reach the originating peer (the Distributor).																						
11	The Distributor displays results to the LO searcher directly or through the SRD																						
<b>EXTENSIONS</b>	<table> <thead> <tr> <th>Step</th> <th>Branching Action</th> </tr> </thead> <tbody> <tr> <td>4a</td> <td>If the request does not reach the gateway, the query request is not sent to the edusource repositories.</td> </tr> <tr> <td>4b</td> <td>The connection to (some of) eduSource repositories is down. ### 3.7 Learning Design Aggregation

This sub-section describes essential operations by which a *Designer* Actor, usually a person such as an instructional designer, a professor, a trainer, a learning object creator, or a software aggregator agent) can use the eduSource infrastructure to create, build and test a unit of learning by aggregating learning objects/resources contained in LO repositories with a learning design.

#### 3.7.1 Learning Design Aggregation Use Cases

A unit of learning is an abstract term used to refer to any delimited piece of education or training, such as a course, a module, a lesson, etc. It can be modeled for example as an IMS Content Package where the organization part is replaced by an IMS Learning Design description.

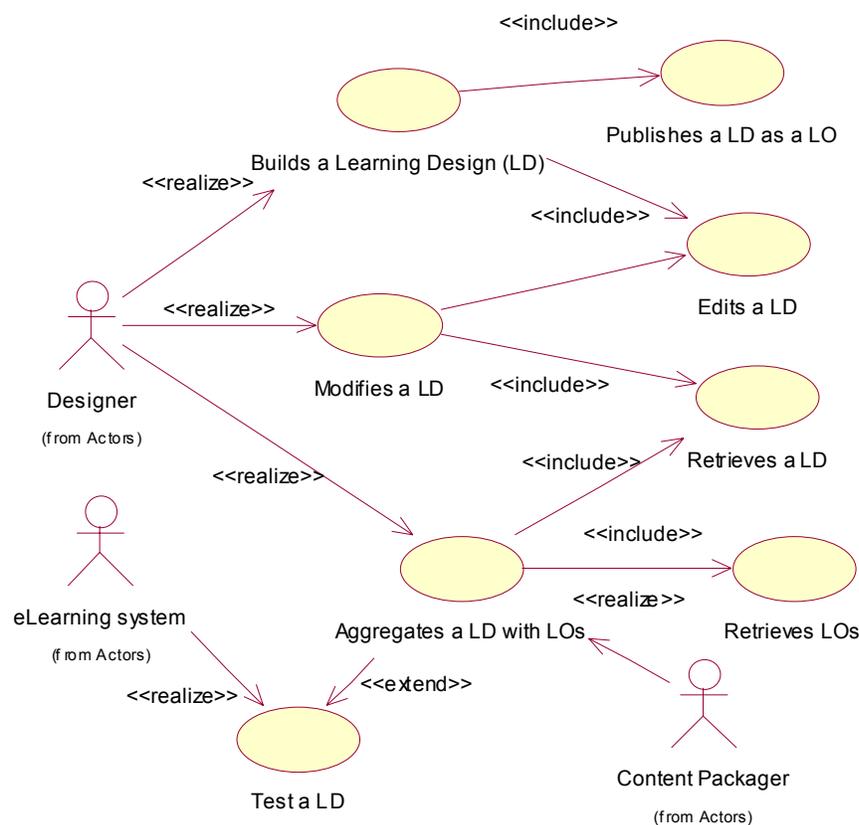

Figure 14 – Learning design sequence diagram

A Learning Design (LD) is composed of an optional title, learning objectives and prerequisites, and metadata referencing the unit of learning as in the IMS content packaging specification. It must have a components and a method part. When activating a unit of learning, the method element is central. It has to be located within the unit of learning set of XML files. This unique element and its sub-elements control the behavior of the unit of learning as a whole, coordinating the activities of the players in the various roles and their use of resources (learning objects). The Method, Plays, Acts and Role-parts are all nested within each other.

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

As shown on the preceding use case diagram, the designer controls four main use cases.

- The Designer builds a Learning Design. This includes editing the method (or instructional scenario) with the help of an *LD Editor*. He then publishes a LD XML file and its metadata in the same way as other learning objects.
- The Designer sometimes modifies an existing LD using the LD Editor. For this, he must be able to retrieve a LD from a metadata repository. This is done using the Search and Display use case, presented earlier
- To be able to validate his design, the Designer has to aggregate the LD with learning objects retrieved from metadata repositories. This is done using a *Content Packager* actor.
- Finally, the Designer will test the result using a LD enabled e-learning system. This system is outside the scope of the eduSource project, but it needs to be represented as an abstract software actor called here the *eLearning System*.

### 3.7.2 Learning Design Aggregation Sequence Diagram

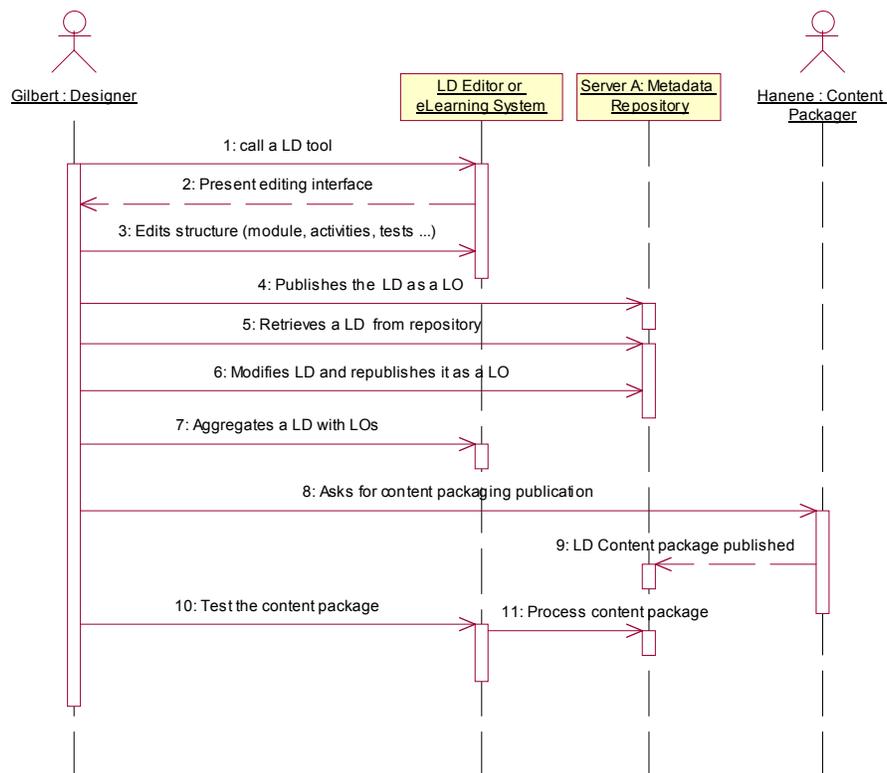

Figure 15 – Learning design sequence diagram

## 3.8 Digital Rights Management

This sub-section describes essential operations by which a LO Publisher can select a Digital Rights Management (DRM) method, enter conditions for users to access the Metadata records and the objects and to process transactions if needed. It also describes the needed operations from the point of view of the user.

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### 3.8.1 Digital Rights Management Use Cases

The Publisher is the main actor. He calls the Provider Broker, a software agent representing a person that wants to publish a new Learning Object to a metadata repository or to modify rights metadata of an existing LO.

The Provider Broker first presents a set of rights metadata models to the Publisher. Each model includes secondary metadata that specify conditions, for example a certain form of payment, that must be fulfilled in order to gain access to the object. The Publisher selects a model and fill out specific conditions that are associated by the Provide Broker to the LO to be integrated by the Repository Builder presented in section 3.5.

A Purchases Broker, a software agent acting on behalf of a person that want to buy access to an object, obtains rights metadata and asks the purchaser (a LO searcher) for payments prescribed in the rights metadata. It sends any required payment to an External Payment System. This system informs the Publisher that sends a credential (a key) to the LO searcher.

## 4. Conceptual View of the Main Packages

This section describes the decomposition of the system into five conceptual packages grouping the uses cases presented in section 3.

### 4.1 Systems's Overview

The UML diagram on figure 18 offers a general functional view of the suite of eduSource software tools and services. In the Center five packages of tools and services compose the infrastructure of the eduSource suite of tools and will be described in the following sections

Three sets of components shown on the figure are outside the frontiers of the eduSource system but use it or are used by it. They delimit the frontiers of the system. On the right side are existing or future e-learning systems, LMS, LCMS, agents or tools that can contribute to build and/or use repositories. On the left side, there are two classes of repositories, one grouping metadata repositories and the other grouping digitized resources. These two classes are separated for the sake of clarity, but it is possible that a repository groups both metadata records and the learning objects they describe.

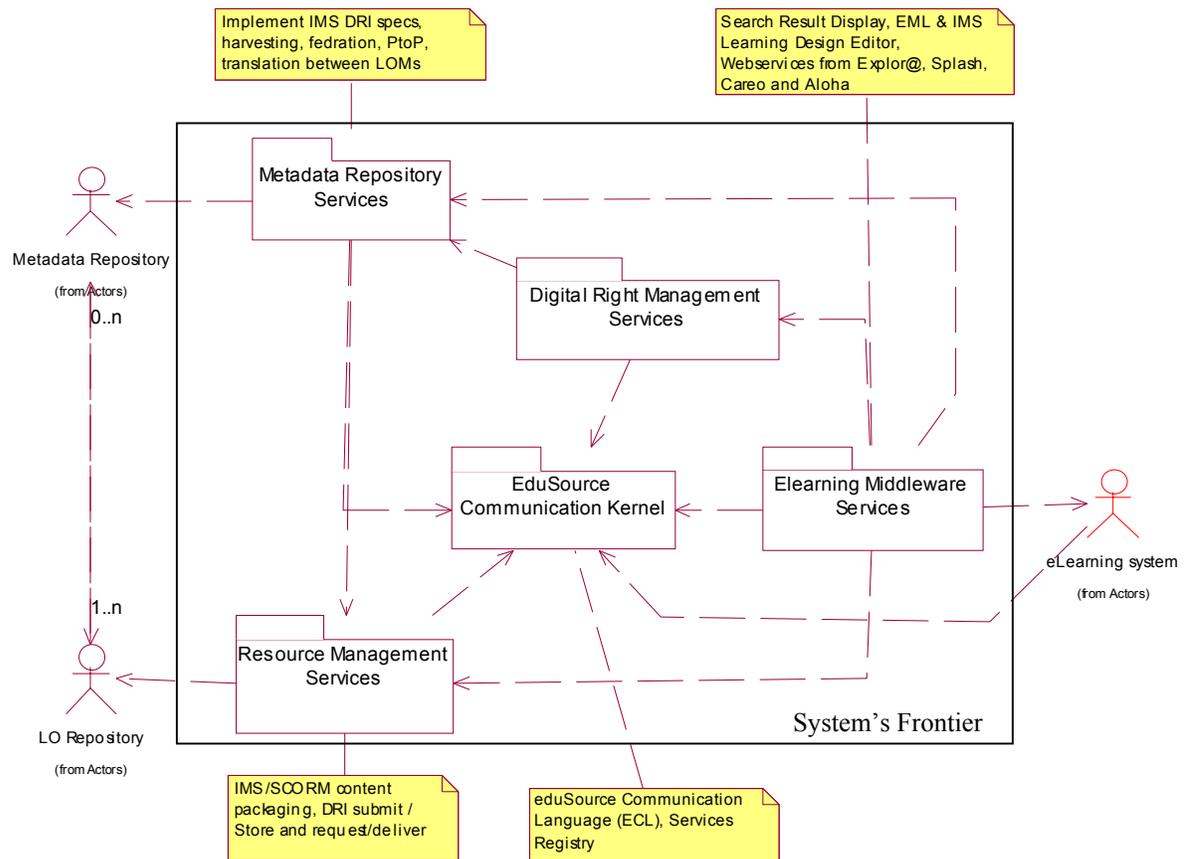

Each *Metadata Repository* groups a set of metadata files referencing educational resources (learning objects). Here we use a very broad definition of a learning object as proposed both in the IEEE LOM and the IMS Design Learning information model. This definition includes the following categories of resources:

- Documents and educational materials, such as multimedia, web pages, texts, software, data records, etc, that hold information and knowledge
- Tools and applications that support the processing of information and knowledge.
- Services sustained by persons such as subject matter experts, trainers, technical assistants, managers.
- Events (or learning opportunities) such as courses, seminars, learning activities, conferences, and discussion group meetings.

Each *Digitized Resource Repository* holds a set of digitized resources: documents and materials, tools and applications. It can also hold digitized information in support to services or events. For example, a course can be described by an Learning Design model that aggregates services from a presenter, delivered on the Web or in a classroom at certain dates, plus learning and assistance scenarios and a set of diversified course materials.

There is a many to many correspondence between metadata repositories and digitized resource (assets) repositories. This is a way to implement a full network approach as opposed to a silo approach. It enables (not require) a metadata repository to reference resources in more than one resource repository and, conversely, it also enables a resource repository to be referenced by more than one metadata repository.

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

**Figure 18 - eduSource general use cases packages**

The system is based on the five use cases packages at the center. They hold the suite of software components that are to be developed, most often through Web services. These services are all referenced in one or more eduSource Web services registries available from the Web. Any service can be called by any eduSource-compliant e-learning system or agent, represented on right side of the figure.

There is no unique central piece in the system and components can be duplicated for redundancy and robustness. Registries can be one or many and services can be offered in more than one version. Of course, the extent of this redundancy will be limited by the 18 months time-frame of the project, but the architecture of the eduSource system will embed these principles right from the start, providing for future evolution.

## 4.2 Communication Kernel

The Communication Kernel includes the eduSource Communication Language (ECL)<sup>1</sup>, a meta-protocol facilitating interactions between tools, services and communication protocols, in particular OAI and

<sup>1</sup> The eduSource Communication Language (ECL) – Working document 0.2, Jean-François Arcand

Z39.50. It also contains the eduSource Services Registry (ESER) that references all the services in the infrastructure, from which a eduSource user can select the services that he wishes to use.

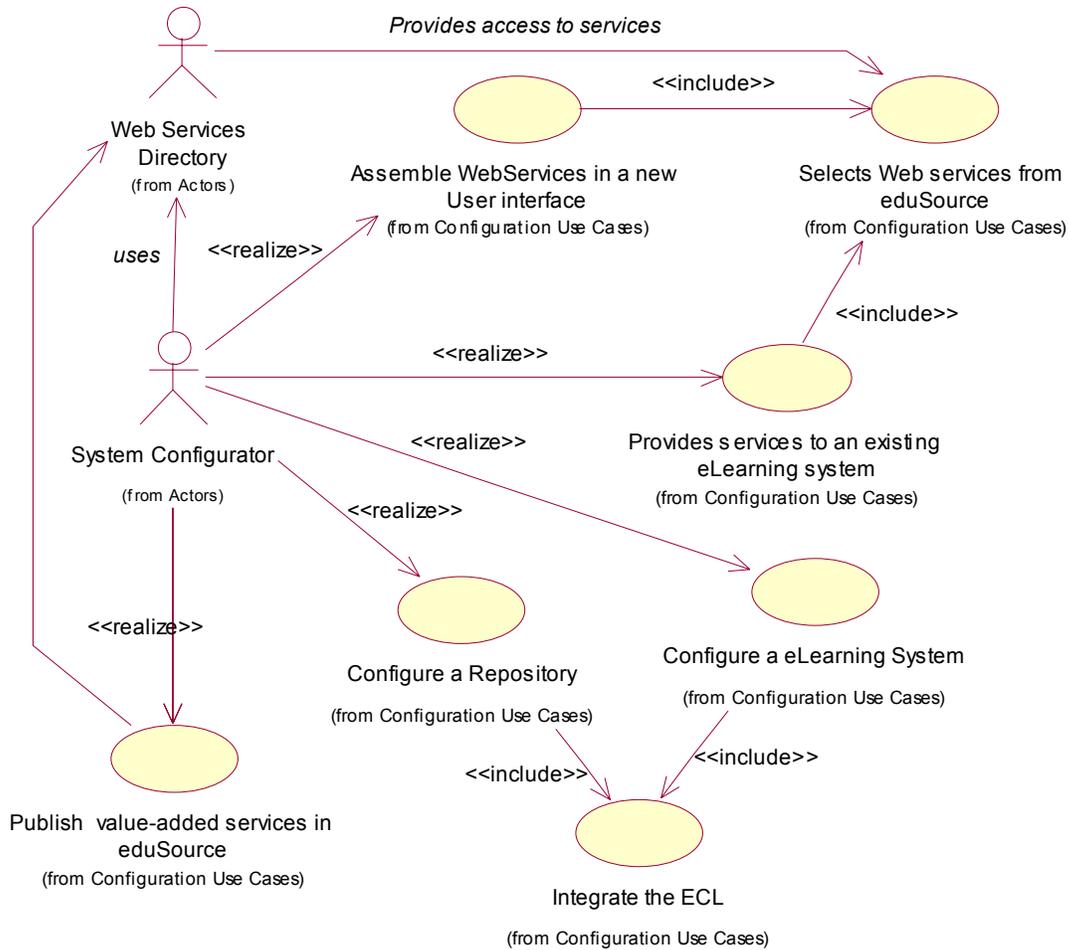

Figure 19 - Use cases in the Communication Kernel

This package groups uses cases around a System Configurator. This actor uses Web services directories to publish value-added services or to select services to be integrated to an existing eLearning system or a new user interface. The System Configurator also integrated the ECL to a repository or to an eLearning system to facilitate the interoperation of communication and metadata protocols.

### 4.3 ELearning Middleware Services

The E-Learning Middleware Services groups all the functionalities enabling users to interact with elearning systems or agents whose providers agree to be referenced in eduSource. Figure 20 shows that services giving access to functionalities in Explor@, Splash, Careo, Aloha, or any other systems can be publishes in the eduSource Webservices registry. It also shows that these services can be integrated in an eduSource enabled eLearning system.

#### 4.4 Metadata Repository Services

Metadata Repository Services is a package that implements the most essential functionalities to fully exploit a set of (partly redundant) metadata repositories. In particular, it will implement some of the IMS Digital Repository Interoperability specs for searching, harvesting, federating such as gather/expose and search/expose, and also peer-to-peer distributed search. It will also include translation services between metadata standards, specifications or profiles such as DC, LOM, CANCORE and MARC, and also between natural languages, starting with French-English translations of metadata.

Figure 21 shows the main Metadata repository services that enable eduSource users to build Metadata repositories and to search such repositories using one or more search methods.

**Figure 21 - Use cases in the Metadata Repository services**

#### 4.5 Resource Management Services

Resource Management Services is a package that takes care of operations needed to launch, aggregate, package, transport the actual resources or learning objects required by any other service or system.

Figure 22 centers these services on an actor called here a designer. Here, the designer retrieves or build a Learning Design and aggregates it with other learning object in the form of an IMS-LD content package or a SCORM package. To enable these operations, other resource management services such as IMS- DRI submit/store and request/deliver will have to be implemented.

#### 4.6 Digital Rights Management Services

Digital Rights Management Services is a package grouping all the components for the management of interactions on digital rights and intellectual property between providers and users of resources and services. As shown on figure 22, it is centered on the interaction between a Publisher, a Provider Broker and a Purchaser Broker.

The Provider Broker enables a learning object Publisher to select a DRM model and produce the associated DRM metadata. The Purchaser Broker provides user identification, payment transactions and authorization to deliver the learning object. It will provide a simple encryption mechanism to secure transactions and adapt the LOM metadata for digital rights managements.

## 5. User Interface View

In this section, we provide general functional specification of the interface needed by the main actors in the system described in the preceding sections, that is the System Configurator, the Metadata Repository Builder, the Learning Objects Searcher, the Designer and the Provider.

We describe each interface from a user's point of view, present the main functions of the interface and sketch a view of a possible instantiation of the interface.

*NB – This section will be completed when a first version of the Software Architecture document will be agreed upon.*

### 5.1 The eduSource Configuration Interface

We center here on the System Configurator's roles.

#### 5.1.1 Description

TBD

#### 5.1.2 Main Functions

TBD

#### 5.1.3 System Configurator's Interface

TBD

### 5.2 A Metadata Repository Builder Interface

We now center on the Metadata Repository Builder's roles.

#### 5.2.1 Description

TBD

#### 5.2.2 Main Functions

TBD

#### 5.2.3 Repository Builder's Interface

TBD

### 5.3 A Search Result Display (SRD) Interface

We now center on the Learning Object Searcher's roles..

#### 5.3.1 Description

TBD

#### 5.3.2 Main Functions

TBD

eduSource Suite of Tools	Version: <0.6>
Uses Cases Specifications	Date: 7-Jun-03

### **5.3.3 LO Searcher's User interface**

TBD

## **5.4 A Design and Package Interface**

We now center on the Designer's roles.

### **5.4.1 Description**

TBD

### **5.4.2 Main Functions**

TBD

### **5.4.3 Designer's User interface**

TBD

## **5.5 A Digital Rights Management Interface**

We finally center on Provider's roles.

### **5.5.1 Description**

TBD

### **5.5.2 Main Functions**

TBD

### **5.5.3 Provider's User interface**

TBD
